In a glass medium, the index of refraction of a blue ray is higher than that for a red ray. Consider red and blue rays through a glass prism.

Compare θ_2^{blue} , θ_2^{red} and θ_3^{blue} , θ_3^{red} .

$$\mathrm{A)} \quad \theta_2^{blue} > \theta_2^{red} \qquad \theta_3^{blue} > \theta_3^{red}$$

$$ext{B)} \quad heta_2^{blue} < heta_2^{red} \qquad heta_3^{blue} > heta_3^{red}$$

$$\begin{array}{ll} \text{B)} & \theta_2^{blue} < \theta_2^{red} & \theta_3^{blue} > \theta_3^{red} \\ \text{C)} & \theta_2^{blue} > \theta_2^{red} & \theta_3^{blue} < \theta_3^{red} \\ \text{D)} & \theta_2^{blue} < \theta_2^{red} & \theta_3^{blue} < \theta_3^{red} \end{array}$$

$$D) \quad \theta_2^{blue} < \theta_2^{red} \qquad \theta_3^{blue} < \theta_3^{red}$$

 $n_{blue} > n_{red}$, so $\theta_2^{blue} < \theta_2^{red}$. In other words, upon entrance into the prism, the blue ray bends more toward the normal.

Inspection of the geometric relations: $\theta_2^{red} + \theta_3^{red} + \beta = 180^{\circ}$ and

$$\theta_2^{blue} + \theta_3^{blue} + \beta = 180^{\circ}$$
 leads to $\theta_3^{blue} > \theta_3^{red}$.

Answer **B**.
